

Two general types of polymerization

- ❑ Addition polymerization

- ❑ Condensation polymerization

Condensation polymers

- ❑ Formed through condensation polymerisation reaction
- ❑ Where molecules join together while losing small molecules as by products
- ❑ In addition polymerization, monomers react to form a polymer without formation of by products

Synthetic polymers

- ❑ Nylon (polyamide)
- ❑ Terylene (polyester)

Nylon formation

- ❑ Made when monomers are combined to form long chain polymer
- ❑ Formed by condensation polymerization
- ❑ Typified by amide group
- ❑ There can be more than one monomer unlike in addition polymerization

Nylon monomers

□ Hexamethylene diamine — monomer

Nylon monomers

□ Adipic acid \Rightarrow monomer

Structure of nylon

⇒ Condensation polymerization of
nylon monomer

Nylon

nylon molecule

Amide linkage in nylon

properties of nylon

- ☐ Toughness
- ☐ Abrasion resistance
- ☐ Easy to wash
- ☐ Easy to dye in wide range
- ☐ High resilience
- ☐ Lustrous

Properties of nylon

- ❑ Most organic solvents have no effect to nylon
- ❑ Little discoloration due to light
- ❑ Elastic
- ❑ Dries quickly
- ❑ Resistance to corrosion and it has high insulation

Types of nylon

- ❑ Nylon 6- formed by ring-opening polymerization
- ❑ Nylon 510- formed from sebacic and pentamethylene diamine acid
- ❑ Nylon 1,6
- ❑ Nylon 66

Uses of nylon

- ❑ Clothing
- ❑ Industries- ropes, tents, seat belts, tents
- ❑ Fish net
- ❑ Machine plastic parts
